Cloud Computing Reference

Cloud computing provides shared resources on demand over a network.

Virtualization separates logical resources from physical hardware.

A virtual machine has an allocated CPU and memory budget.

Consumers retain responsibilities that depend on the service model.

Model	Consumer responsibility	Provider responsibility
IaaS	Operating system	Physical hardware
PaaS	Application code	Runtime
SaaS	Access policy	Application platform

```
Memory budget = 4 * 8 = 32 GB
```

```
const instances = 4;
return instances * 8;
```

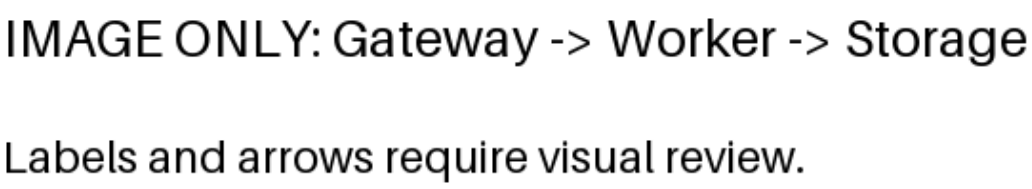

Figure 1: Flattened architecture labels need visual review.

Two columns: resource assumptions

CPU is a processing resource.

RAM stores working data.

Storage retains persistent data.

Capacity limits need explicit units.

A network connects components.

Latency measures waiting time.

Bandwidth measures data per second.

Service levels require source context.
